

NAME

bind – bind a name to a socket

LIBRARY

Standard C library (*libc*, *-lc*)

SYNOPSIS

```
#include <sys/socket.h>
```

```
int bind(int sockfd, const struct sockaddr *addr,
         socklen_t addrlen);
```

DESCRIPTION

When a socket is created with **socket(2)**, it exists in a name space (address family) but has no address assigned to it. **bind()** assigns the address specified by *addr* to the socket referred to by the file descriptor *sockfd*. *addrlen* specifies the size, in bytes, of the address structure pointed to by *addr*. Traditionally, this operation is called “assigning a name to a socket”.

It is normally necessary to assign a local address using **bind()** before a **SOCK_STREAM** socket may receive connections (see **accept(2)**).

The rules used in name binding vary between address families. Consult the manual entries in Section 7 for detailed information. For **AF_INET**, see **ip(7)**; for **AF_INET6**, see **ipv6(7)**; for **AF_UNIX**, see **unix(7)**; for **AF_APPLETALK**, see **ddp(7)**; for **AF_PACKET**, see **packet(7)**; for **AF_X25**, see **x25(7)**; and for **AF_NETLINK**, see **netlink(7)**.

The actual structure passed for the *addr* argument will depend on the address family. The *sockaddr* structure is defined as something like:

```
struct sockaddr {
    sa_family_t sa_family;
    char        sa_data[14];
}
```

The only purpose of this structure is to cast the structure pointer passed in *addr* in order to avoid compiler warnings. See **EXAMPLES** below.

RETURN VALUE

On success, zero is returned. On error, *-1* is returned, and *errno* is set to indicate the error.

ERRORS**EACCES**

The address is protected, and the user is not the superuser.

EADDRINUSE

The given address is already in use.

EADDRINUSE

(Internet domain sockets) The port number was specified as zero in the socket address structure, but, upon attempting to bind to an ephemeral port, it was determined that all port numbers in the ephemeral port range are currently in use. See the discussion of */proc/sys/net/ipv4/ip_local_port_range* **ip(7)**.

EBADF

sockfd is not a valid file descriptor.

EINVAL

The socket is already bound to an address.

EINVAL

addrlen is wrong, or *addr* is not a valid address for this socket’s domain.

ENOTSOCK

The file descriptor *sockfd* does not refer to a socket.

EADDRNOTAVAIL

A nonexistent interface was requested or the requested address was not local.

The following errors are specific to UNIX domain (**AF_UNIX**) sockets:

EACCES

Search permission is denied on a component of the path prefix. (See also **path_resolution(7)**.)

EFAULT

addr points outside the user's accessible address space.

ELOOP

Too many symbolic links were encountered in resolving *addr*.

ENAMETOOLONG

addr is too long.

ENOENT

A component in the directory prefix of the socket pathname does not exist.

ENOMEM

Insufficient kernel memory was available.

ENOTDIR

A component of the path prefix is not a directory.

EROFS

The socket inode would reside on a read-only filesystem.

Other errors may be generated by the underlying protocol modules.

VERSIONS

Portable programs must ensure that *addr.sun_path* is a null-terminated string for **AF_UNIX** sockets.

STANDARDS

POSIX.1-2024.

HISTORY

POSIX.1-2001, SVr4, 4.2BSD.

BUGS

The transparent proxy options are not described.

EXAMPLES

An example of the use of **bind()** with Internet domain sockets can be found in **getaddrinfo(3)**.

The following example shows how to bind a stream socket in the UNIX (**AF_UNIX**) domain, and accept connections:

```
#include <err.h>
#include <stdlib.h>
#include <string.h>
#include <sys/socket.h>
#include <sys/un.h>
#include <unistd.h>

#define MY SOCK_PATH "/somepath"
#define LISTEN_BACKLOG 50

int
main(void)
{
    int                sfd, cfd;
    socklen_t          peer_addr_size;
    struct sockaddr_un  my_addr, peer_addr;
```

```
sfd = socket(AF_UNIX, SOCK_STREAM, 0);
if (sfd == -1)
    err(EXIT_FAILURE, "socket");

memset(&my_addr, 0, sizeof(my_addr));
my_addr.sun_family = AF_UNIX;
strncpy(my_addr.sun_path, MY SOCK_PATH,
        sizeof(my_addr.sun_path) - 1);

if (bind(sfd, (struct sockaddr *) &my_addr,
        sizeof(my_addr)) == -1)
    err(EXIT_FAILURE, "bind");

if (listen(sfd, LISTEN_BACKLOG) == -1)
    err(EXIT_FAILURE, "listen");

/* Now we can accept incoming connections one
   at a time using accept(2). */

peer_addr_size = sizeof(peer_addr);
cfd = accept(sfd, (struct sockaddr *) &peer_addr,
            &peer_addr_size);
if (cfd == -1)
    err(EXIT_FAILURE, "accept");

/* Code to deal with incoming connection(s)... */

if (close(sfd) == -1)
    err(EXIT_FAILURE, "close");

if (unlink(MY SOCK_PATH) == -1)
    err(EXIT_FAILURE, "unlink");
}
```
